# Motivation

- We want to access, creating priority hierarchy on the access of the nodes of a directed acyclic graph in a certain way that there are lines connected between each other. But, how to do it?

# Topological Sort!

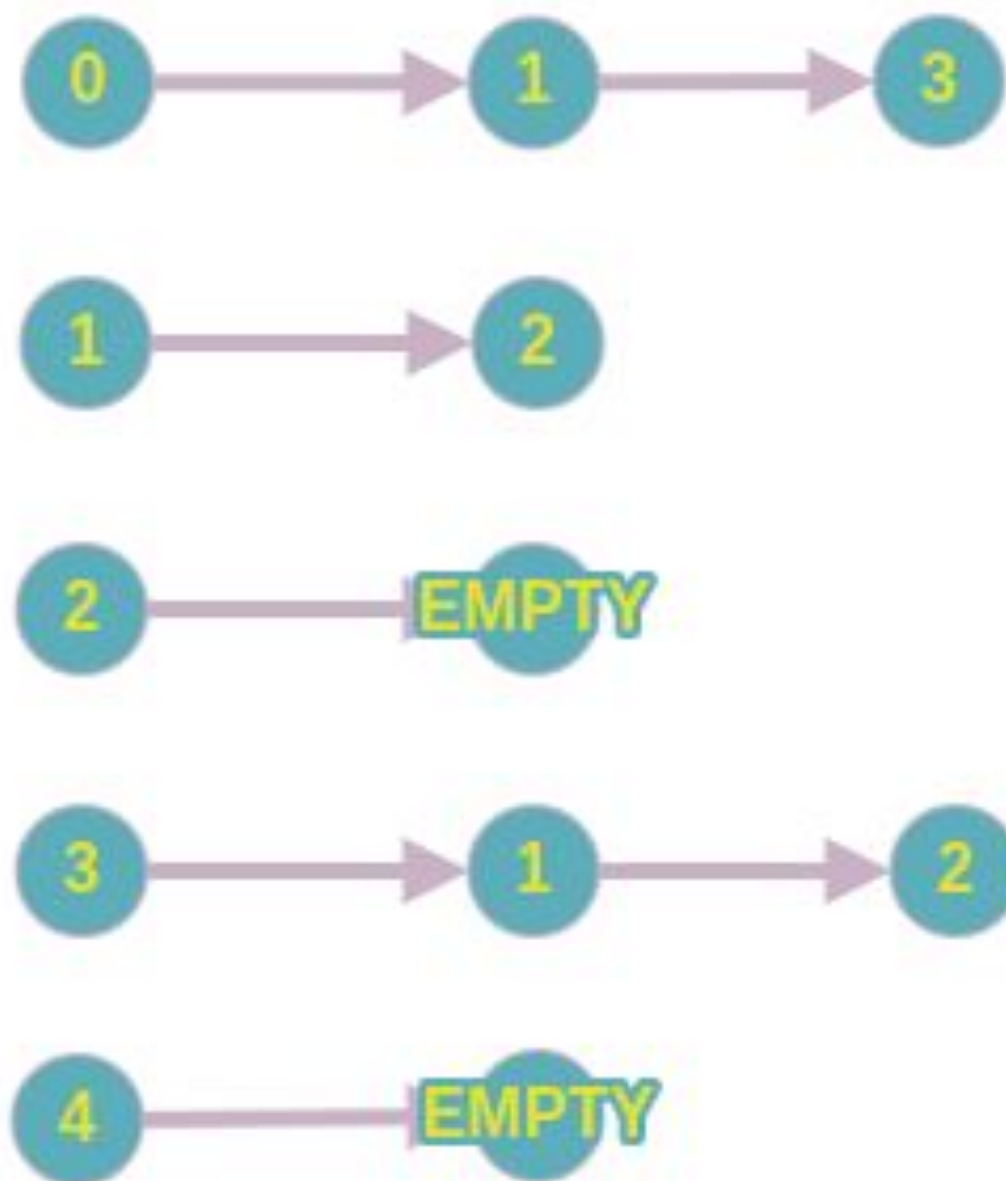

# Topological Sort

- It is a DFS(depth-first search) in a directed acyclic graph that seeks topological sorting (priority sorting).
- The need of creating access priorities in those graphs in a certain way that a vertex  $uv$  (a vertex  $u$  to a vertex  $v$ ) comes before  $v$  in the visitation order.

# Code

```
void TopologicalSort(GRAPH *graph, STACK *stack, int
source){
    graph->visited[source] = 1;
    NODE *adj_list = graph->vertices[source];
    while(adj_list != NULL){
        if(!graph->visited[adj_list->value] {
            TopologicalSort(graph,stack,adj_list->value);
        }
        adj_list = adj_list->next;
    }
    push(stack,value);
}
```

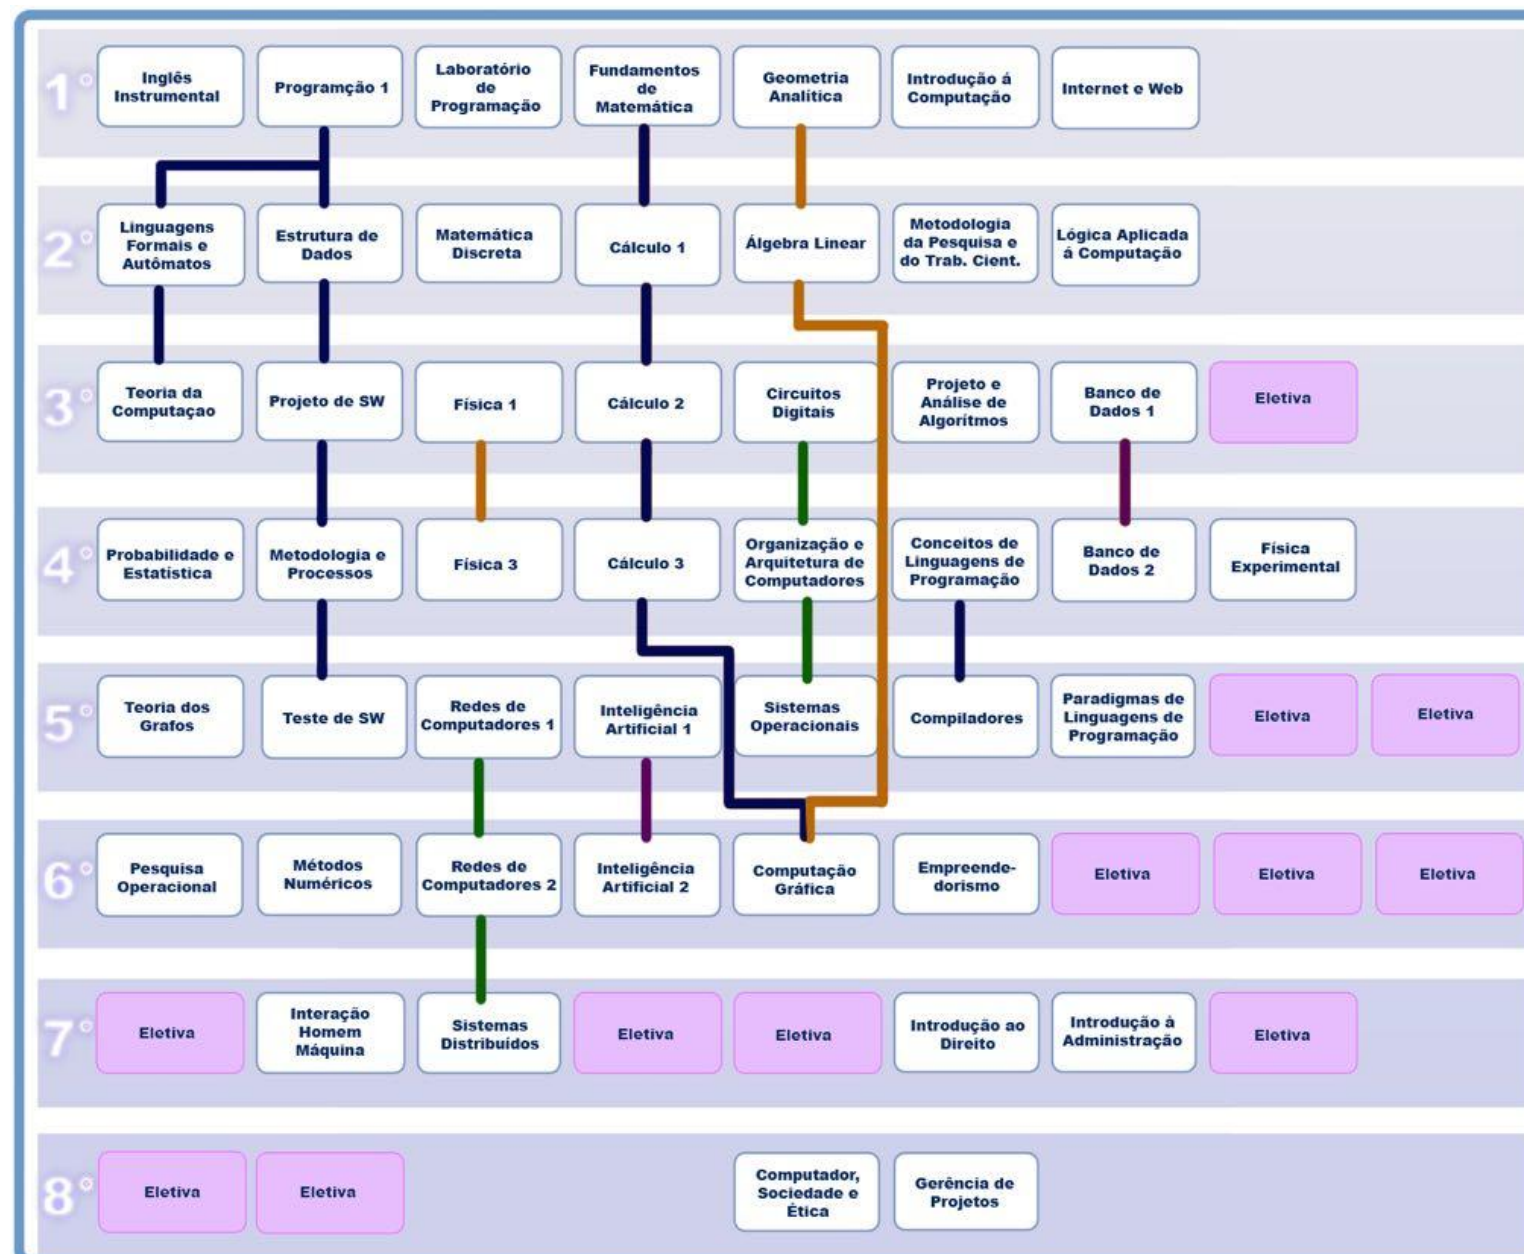

# Back to the motivation...

- Why does the Topological Sort algorithm solved the described problem?

# Applications

- apt get
- Hierarchy between disciplines in the curriculum grades

**Muito obrigado pela  
atenção!**
